

A new type of colony in Silurian (upper Wenlock) retiolitid graptolite *Spinograptus* from Poland

Anna Kozłowska, Kinga Dobrowolska, and Denis E.B. Bates *Acta Palaeontologica Polonica* 58 (1), 2013: 85-92 doi: http://dx.doi.org/10.4202/app.2011.0020

The new retiolitid species, *Spinograptus tubothecalis*, is described from the *Colonograptus praedeubeli* and *C. deubeli* biozones from two localities in Poland: a borehole on the East European Platform and the Holy Cross Mountains. This was a recovery phase after the severe Silurian *Cyrtograptus lundgreni* Event. The new species has a unique, previously undescribed form of finite rhabdosome. Unlike the species *Spinograptus reticulolawsoni* and *S. lawsoni*, in which the finite rhabdosomes taper distally, its rhabdosome is parallel–sided with the two distal thecae developed as isolated tubes without genicular processes, with a small appendix between them. The new species also has preserved membranes of the sicula, thecae and ancora sleeve, similar to a few species of *Spinograptus* from the lower Homerian. *Spinograptus tubothecalis*, like *Spinograptus clathrospinosus* and *S. spinosus*, has paired reticulofusellar genicular processes on the pre–thecal ventral orifices, similar to but shorter than thecal processes. Transverse rods, a rare character in post–*Cyrtograptus lundgreni* Event retiolitids occur in the new species in rudimentary form.

Key words: Graptoloidea, Retiolitidae, Spinograptus, finite colony, Silurian, Poland.
