Acta Palaeontologica Polonica 57 (1), 2012: 85-100 doi: <http://dx.doi.org/10.4202/app.2010.0075>

Postcranial skeletal pneumaticity (PSP) is present in a range of basal sauropodomorphs spanning the basal sauropodomorph–sauropod transition. We describe the PSP of five taxa, *Plateosaurus engelhardti*, *Eucnemesaurus fortis*, *Aardonyx celestae*, *Antetonitrus ingenipes*, and an unnamed basal sauropod from Spion Kop, South Africa (hereafter referred to as the Spion Kop sauropod). The PSP of *Plateosaurus* is apparently sporadic in its occurrence and has only been observed in very few specimens, in which it is of very limited extent, affecting only the posterior cervical vertebrae and possibly the mid dorsals in one specimen. The PSP of *Eucnemesaurus*, *Aardonyx*, *Antetonitrus*, and the Spion Kop sauropod consists of subfossae (fossa–within–fossa structures) that excavate the vertices of the posterior infradiapophyseal fossae of the posterior dorsal vertebrae. These subfossae range from simple shallow depressions (*Eucnemesaurus*) to deep, steep-sided, internally subdivided and asymmetrically developed chambers (*Antetonitrus*). The middle and anterior dorsal vertebrae of these taxa lack PSP, demonstrating that abdominal air sacs were the source of the invasive diverticula. The presence of pneumatic features within the infradiapophyseal fossae suggest that the homologous fossae of more basal saurischians and dinosauriforms were receptacles that housed pneumatic diverticula. We suggest that it is probable that rigid non-compliant lungs ventilated by compliant posterior air sacs evolved prior to the origination of Dinosauria.

Key words: Sauropodomorpha, Sauropoda, postcranial skeletal pneumaticity, air-sacs, Triassic, Jurassic, South Africa.
