

A new short-legged landbird from the early Eocene of Wyoming and contemporaneous European sites

Gerald Mayr and Michael Daniels *Acta Palaeontologica Polonica* 46 (3), 2001: 393-402

Fluvioviridavis platyrhamphus, a new genus and species of short-legged landbirds from the Lower Eocene Green River Formation (Wyoming, USA) is described. The taxon is known from a single, nearly complete and slightly dissociated skeleton which was made the paratype of the putative oilbird Prefica nivea Olson, 1987 (Steatornithidae, Caprimulgiformes). Apart from the greatly abbreviated tarsometatarsus, Fluvioviridavis especially corresponds to recent oilbirds in the unusually wide proximal end of the humerus. However, in other features, e.g., the shape of its much longer beak, the Eocene taxon is clearly distinguished from the recent oilbird (Steatornis). In contrast, Prefica nivea agrees with Steatornis in the shape of the mandible but differs in the much narrower proximal end of the humerus. At present, no derived character convincingly supports a classification of F. platyrhamphus into any of the higher avian taxa. The species is here classified order and family incertae sedis An isolated skull from the Middle Eocene of Messel (Hessen, Germany) is tentatively assigned to ?Fluvioviridavis sp., and associated bones from the Lower Eocene London Clay of Walton-on-the-Naze (Essex, England) might also be related to the genus Fluvioviridavis.

Key words: Fossil birds, Eocene, Fluvioviridavis, Green River Formation, Messel, London Clay.
